- Midterm practical problems posted
- HW04 posted (work individually)

Pandas

Pandas

Open source library for data handling and manipulation in high-performance environments.

Installation If you are using Anaconda package manager,

```
conda install pandas
```

Or if you are using PyPi (pip) package manager,

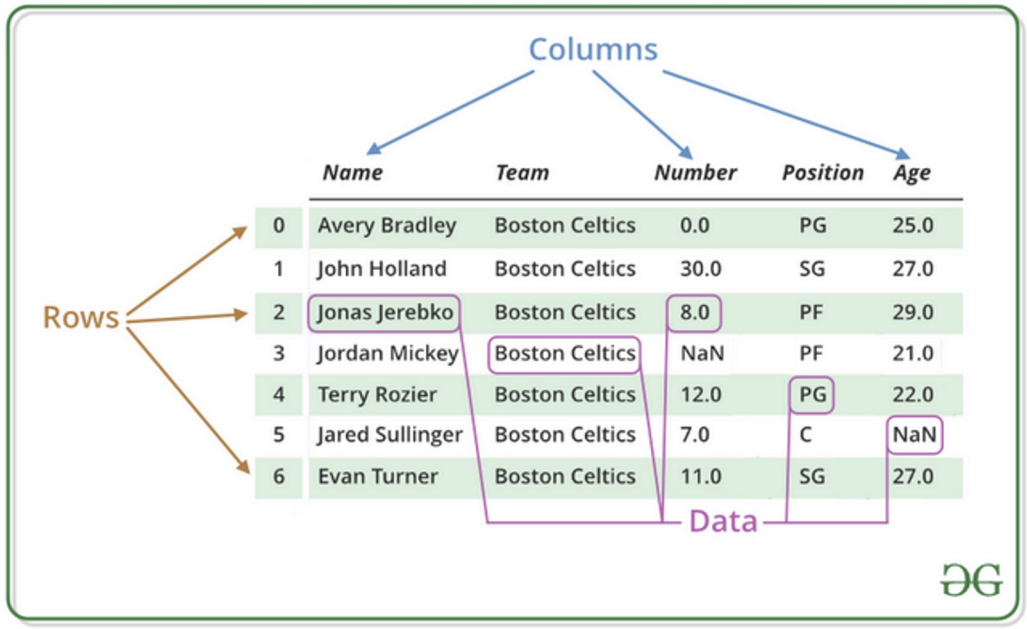
```
pip install pandas
```

See Pandas documentation for more detailed instructions

https://pandas.pydata.org/docs/getting_started/install.html

DataFrame

Primary data structure : Essentially a table



Q: how is it different from numpy array?

- Numpy arrays are more efficient
- Pandas dataframes are more flexible

DataFrame Example

Create and print an entire DataFrame

```
# import pandas as pd
import pandas as pd

# list of strings
lst = ['Geeks', 'For', 'Geeks', 'is',
            'portal', 'for', 'Geeks']

# Calling DataFrame constructor on list
df = pd.DataFrame(lst)
print(df)
```

	0
0	Geeks
1	For
2	Geeks
3	is
4	portal
5	for
6	Geeks

DataFrame Example

Can create named columns using dictionary

```
import pandas as pd

# intialise data of lists.
data = {'Name':['Tom', 'nick', 'krish', 'jack'],
        'Age':[20, 21, 19, 18]}

# Create DataFrame
df = pd.DataFrame(data)

# Print the output.
print(df)
```

	Name	Age
0	Tom	20
1	nick	21
2	krish	19
3	jack	18

all data must have the same length

DataFrame : Selecting Columns

Select columns to print by name,

```
# Import pandas package
import pandas as pd

# Define a dictionary containing employee data
data = {'Name':['Jai', 'Princi', 'Gaurav', 'Anuj'],
        'Age':[27, 24, 22, 32],
        'Address':['Delhi', 'Kanpur', 'Allahabad', 'Kannauj'],
        'Qualification':['Msc', 'MA', 'MCA', 'Phd']}

# Convert the dictionary into DataFrame
df = pd.DataFrame(data)

# select two columns
print(df[['Name', 'Qualification']])
```

	Name	Qualification
0	Jai	Msc
1	Princi	MA
2	Gaurav	MCA
3	Anuj	Phd

access columns by name, not the column index!

DataFrame : Selecting Columns

[35]:
```
import pandas as pd
data = {'Name': ['tom', 'nick'], 'Age': [10,20]}
df = pd.DataFrame(data)
```

[36]:
```
df[['Name']]
```

[36]:

	Name
0	tom
1	nick

[37]:
```
df['Name']
```

[37]:
```
0     tom
1    nick
Name: Name, dtype: object
```

[38]:
```
type(df[['Name']]), type(df['Name'])
```

[38]:
```
(pandas.core.frame.DataFrame, pandas.core.series.Series)
```

still a DataFrame

essentially, a ‘named’ array

pandas.Series

class **pandas.Series**(*data=None, index=None, dtype=None, name=None, copy=False, fastpath=False*) [source]

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

DataFrame : Selecting Rows

```python
import pandas as pd
import numpy as np

# Define a dictionary containing employee data
data = {'Name':['Jai', 'Princi', 'Gaurav', 'Anuj'],
        'Age':[27, 24, 22, 32],
        'Address':['Delhi', 'Kanpur', 'Allahabad', 'Kannauj'],
        'Qualification':['Msc', 'MA', 'MCA', 'Phd']}

# Convert the dictionary into DataFrame
df = pd.DataFrame(data)

# Print rows 1 & 2
row = df.loc[1:2]
print(row)
```

2nd and 3rd row!

1:2 includes 2! annoying! this is not python standard!!!

Output

	Name	Age	Address	Qualification
1	Princi	24	Kanpur	MA
2	Gaurav	22	Allahabad	MCA

(still a DataFrame)

DataFrame : Selecting Rows

[6]:
```
import pandas as pd
data = {'Name': ['tom', 'nick'], 'Age': [10,20]}
df = pd.DataFrame(data)
```

[19]:
```
df.loc[1:1]
```

[19]:

	Name	Age
1	nick	20

[20]:
```
df.loc[1]
```

[20]:
```
Name    nick
Age       20
Name: 1, dtype: object
```

[21]:
```
type(df.loc[1:1]), type(df.loc[1])
```

[21]:
```
(pandas.core.frame.DataFrame, pandas.core.series.Series)
```

- df.loc[1:1] is DataFrame object
- df.loc[1] is a series

DataFrame : Selecting Rows

`head()` and `tail()` select rows from beginning / end

```
import pandas as pd
import numpy as np

# Define a dictionary containing employee data
data = {'Name':['Jai', 'Princi', 'Gaurav', 'Anuj'],
        'Age':[27, 24, 22, 32],
        'Address':['Delhi', 'Kanpur', 'Allahabad', 'Kannauj'],
        'Qualification':['Msc', 'MA', 'MCA', 'Phd']}

# Convert the dictionary into DataFrame
df = pd.DataFrame(data)

# Print first / last rows
first2 = df.head(2)
last2 = df.tail(2)
print(first2)
print('\n', last2)
```

Output

```
     Name  Age Address Qualification
0     Jai   27   Delhi           Msc
1  Princi   24  Kanpur            MA

      Name  Age    Address Qualification
2  Gaurav   22  Allahabad           MCA
3    Anuj   32    Kannauj           Phd
```

Reading Data from Files

Easy reading / writing of standard formats,

```
df = pd.read_json("data.json")
print(df)
df.to_csv("data.csv", index=False)
df_csv = pd.read_csv("data.csv")
print(df_csv.head(2))
```

example: twitter api returns search results in json format.

index ↓

Output

```
     Duration  Pulse  Maxpulse  Calories
0          60    110       130     409.1
1          60    117       145     479.0
2          60    103       135     340.0
3          45    109       175     282.4
4          45    117       148     406.0
..        ...    ...       ...       ...
164        60    105       140     290.8
165        60    110       145     300.4
166        60    115       145     310.2
167        75    120       150     320.4
168        75    125       150     330.4

[169 rows x 4 columns]
   Duration  Pulse  Maxpulse  Calories
0        60    110       130     409.1
1        60    117       145     479.0
```

Data Structure Conversions

Working with DataFrames outside of Pandas can be tricky,

```
df['Duration']
```

Q: does it return a DataFrame object or Series object?

```
0      60
1      60
2      60
3      45
4      45
      ..
164    60
165    60
166    60
167    75
168    75
Name: Duration, Length: 169, dtype: int64
```

We can easily convert to built-in types, for example to a list.

```
L = df['Duration'].to_list()
print(L)
```

```
[60, 60, 60, 45, 45, 60, 60, 45, 30, 60, 60, 60, 60, 60, 60, 60, 60, 45, 60, 45, 60, 45, 60, 45, 60, 60, 60, 60, 60,
60, 60, 45, 60, 60, 60, 60, 60, 60, 60, 45, 45, 60, 60, 60, 60, 60, 60, 45, 45, 60, 60, 80, 60, 60, 30, 60, 60, 45, 2
0, 45, 210, 160, 160, 45, 20, 180, 150, 150, 20, 300, 150, 60, 90, 150, 45, 90, 45, 45, 120, 270, 30, 45, 30, 120, 4
5, 30, 45, 120, 45, 20, 180, 45, 30, 15, 20, 20, 30, 25, 30, 90, 20, 90, 90, 90, 30, 30, 180, 30, 90, 210, 60, 45, 1
5, 45, 60, 60, 60, 60, 60, 60, 30, 45, 60, 60, 60, 60, 60, 60, 90, 60, 60, 60, 60, 60, 60, 20, 45, 45, 45, 20, 60, 6
0, 45, 45, 60, 45, 60, 60, 30, 60, 60, 60, 60, 30, 60, 60, 60, 60, 60, 30, 30, 45, 45, 45, 60, 60, 60, 75, 75]
```

Data Structure Conversions

Or, to a numpy array.

```
[6]: import pandas as pd
     data = {'Name': ['tom', 'nick'], 'Age': [10,20]}
     df = pd.DataFrame(data)
```

```
[29]: df
```

[29]:

	Name	Age
0	tom	10
1	nick	20

```
[31]: df.to_numpy()

[31]: array([['tom', 10],
             ['nick', 20]], dtype=object)
```

```
[40]: df['Name'].to_numpy()

[40]: array(['tom', 'nick'], dtype=object)
```

`to_numpy()`: defined on `Index`, `Series`, and `DataFrame` objects

Summary Statistics

Easily compute summary statistics on data

```
print('Min: ', df['Duration'].min())
print('Max: ', df['Duration'].max())
print('Median: ', df['Duration'].median())
```

```
Min:  15
Max:  300
Median:  60.0
```

Can also count occurrences of unique values,

```
df['Duration'].value_counts()
```

```
60     79
45     35
30     16
20      9
90      8
150     4
120     3
180     3
15      2
75      2
160     2
210     2
270     1
25      1
300     1
80      1
Name: Duration, dtype: int64
```

s = df['Duration'].value_counts()
s[60]=79.

Summary Statistics

[42]:
```
import pandas as pd
data = {'Name': ['tom', 'nick'], 'Age': [10,20], 'Height': [6.2, 5.5]}
df = pd.DataFrame(data)
df
```

[42]:

	Name	Age	Height
0	tom	10	6.2
1	nick	20	5.5

[43]:
```
df.describe()
```

[43]:

	Age	Height
count	2.000000	2.000000
mean	15.000000	5.850000
std	7.071068	0.494975
min	10.000000	5.500000
25%	12.500000	5.675000
50%	15.000000	5.850000
75%	17.500000	6.025000
max	20.000000	6.200000

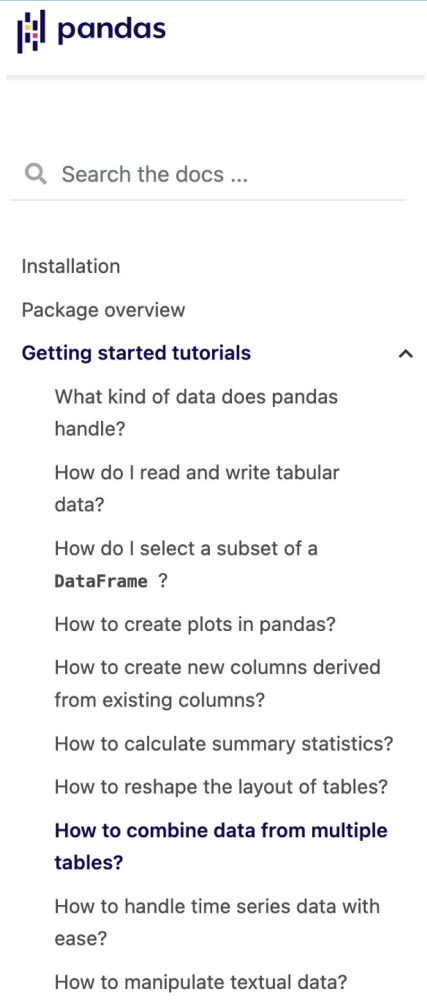
use describe() to get a summary of the data

More on Pandas

Many database operations are available

- You can specify index, which can speed up some operations
- You can do ‘join’
- You can do ‘where’ clause to filter the data
- You can do ‘group by’

More on Pandas



Doing it by yourself helps a lot!

Data Visualization

Outline

Visual Perception

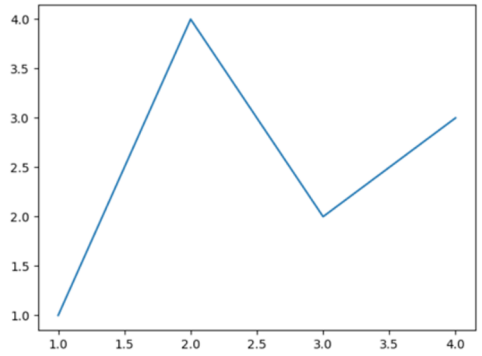
Understanding

Data visualization in Python…

```
import matplotlib.pyplot as plt
import numpy as np
```

Create a simple figure with an axis object,

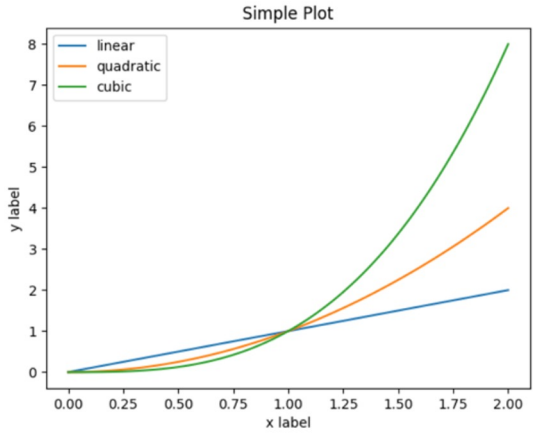
```
fig, ax = plt.subplots()  # Create a figure containing a single axes.
ax.plot([1, 2, 3, 4], [1, 4, 2, 3])  # Plot some data on the axes.
```



A more complicated plot…

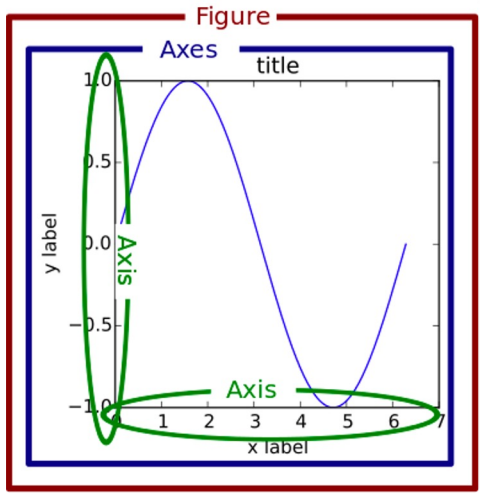
```
x = np.linspace(0, 2, 100)

# Note that even in the OO-style, we use `.pyplot.figure` to create the figure.
fig, ax = plt.subplots()  # Create a figure and an axes.
ax.plot(x, x, label='linear')  # Plot some data on the axes.
ax.plot(x, x**2, label='quadratic')  # Plot more data on the axes...
ax.plot(x, x**3, label='cubic')  # ... and some more.
ax.set_xlabel('x label')  # Add an x-label to the axes.
ax.set_ylabel('y label')  # Add a y-label to the axes.
ax.set_title("Simple Plot")  # Add a title to the axes.
ax.legend()  # Add a legend.
```



matplotlib

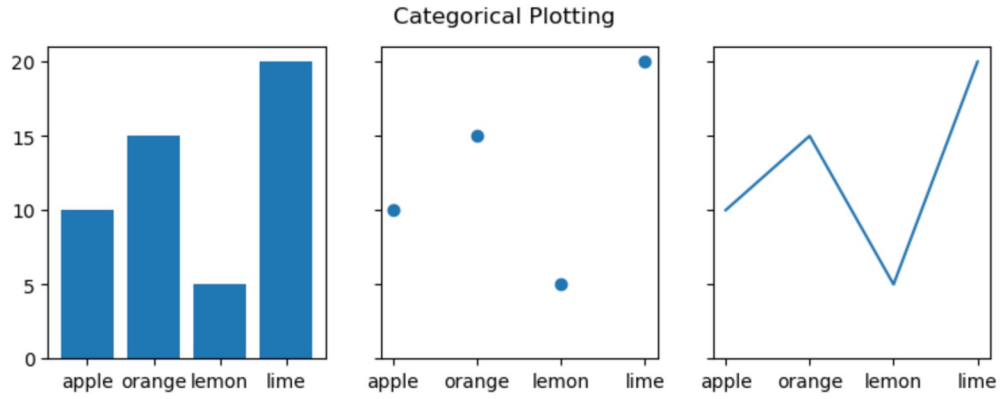
Axes vs Axis

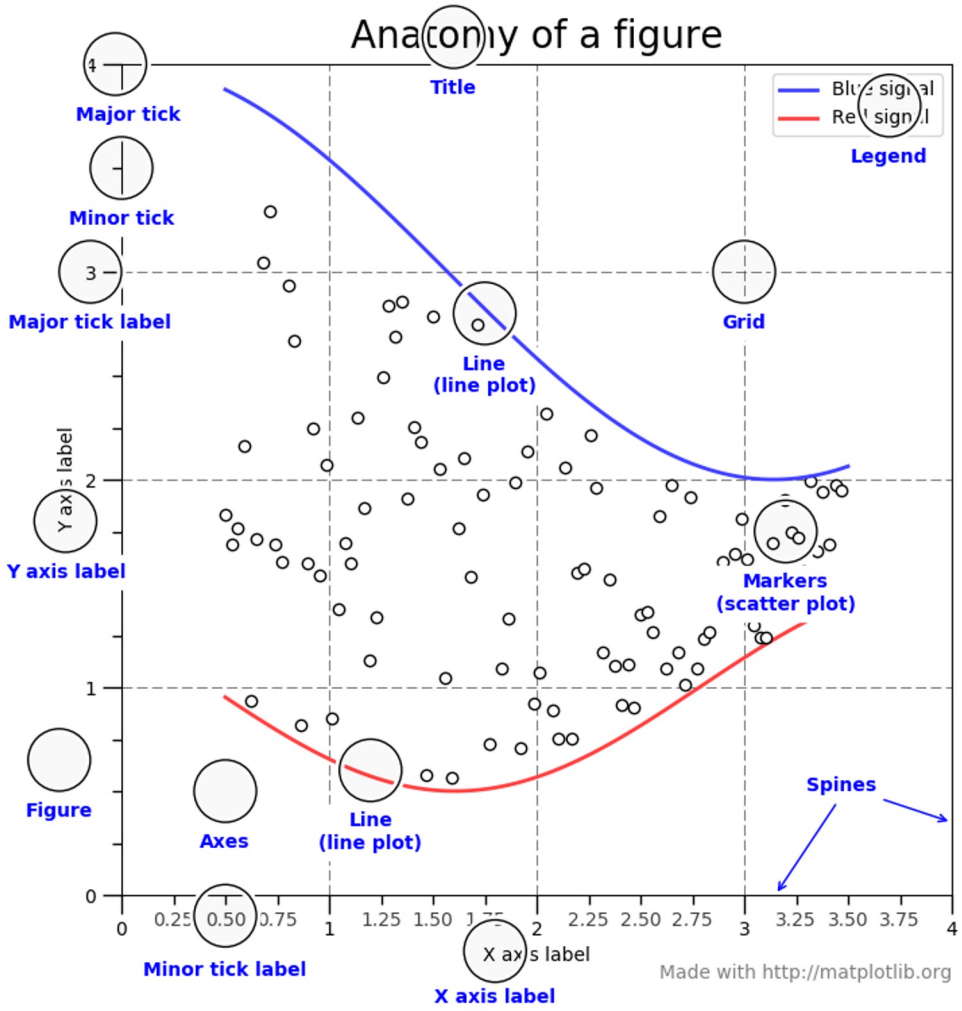


`subplot()` function: draw multiple plots in one figure

```
data = {'apple': 10, 'orange': 15, 'lemon': 5, 'lime': 20}
names = list(data.keys())
values = list(data.values())

fig, axs = plt.subplots(1, 3, figsize=(9, 3), sharey=True)
axs[0].bar(names, values)
axs[1].scatter(names, values)
axs[2].plot(names, values)
fig.suptitle('Categorical Plotting')
```



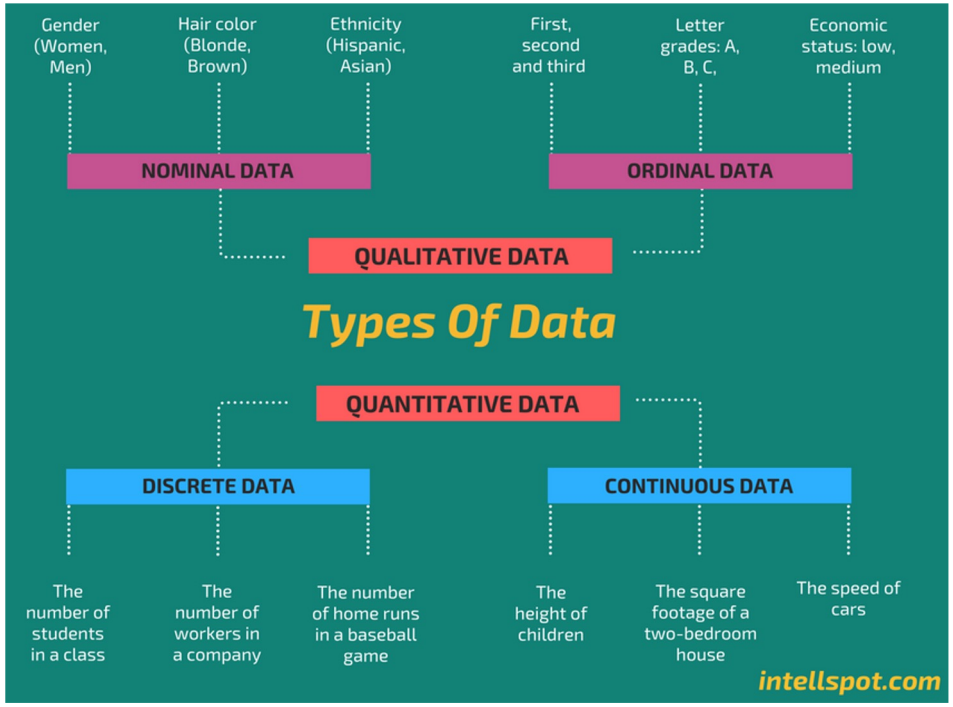


components of a Matplotlib figure

Documentation + tutorials:
https://matplotlib.org/

Types of Data

Data come in many forms, each requiring different approaches & models



Qualitative or **categorical** : can partition data into classes

Quantitative : can perform mathematical operations (e.g., addition, subtraction, ordering)

*We often refer to different types of data as **variables***

Categorical Variables

Examples

- Roll of a die: 1,2,3,4,5 or 6
- Blood Type: A, B, AB, or O
- Political Party: Democrat, Republican, etc.
- Type of Rock: Igneous, Sedimentary, or Metamorphic
- Word Identity: NP, VP, N, V, Adj, Adv, etc.

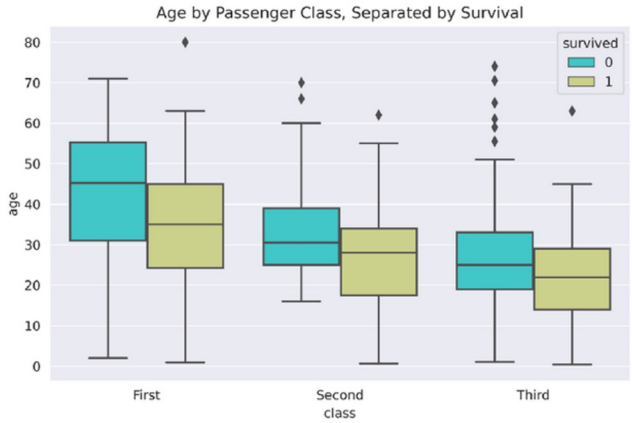
Numerical data can be categorical or quantitative depending on context

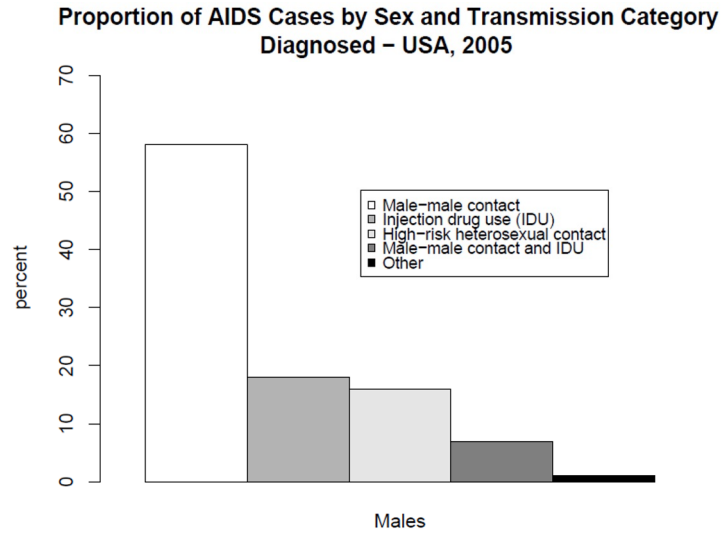
Conversion: Quantitative data can be converted to categorical by defining ranges:

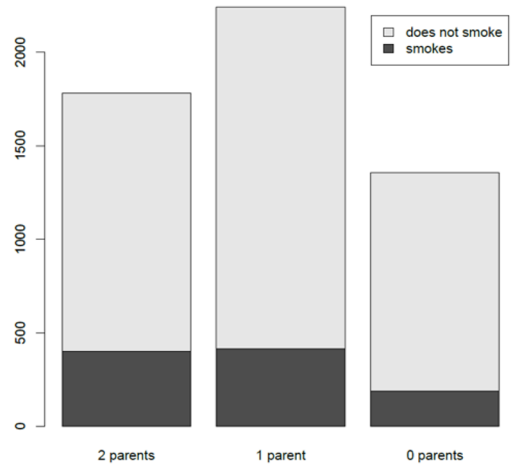
- Small [0, 10cm), Medium [10, 100cm), Large [100cm, 1m), XL [1m, -)
- Low [less than -100dB), Moderate [-100dB, -50dB), Loud [over -50dB)

Visualizing Categorical Variables

	student smokes	student does not smoke	total
2 parents smoke	400	1380	1780
1 parent smokes	416	1823	2239
0 parents smoke	188	1168	1356
total	1004	4371	5375







Pie Chart

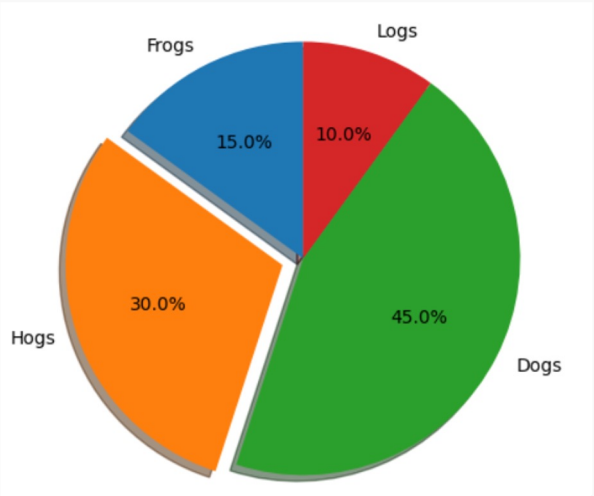
Circular chart divided into sectors, illustrating relative magnitudes in frequencies or percentage. In a pie chart, the area is proportional to the quantity it represents.

```python
import matplotlib.pyplot as plt

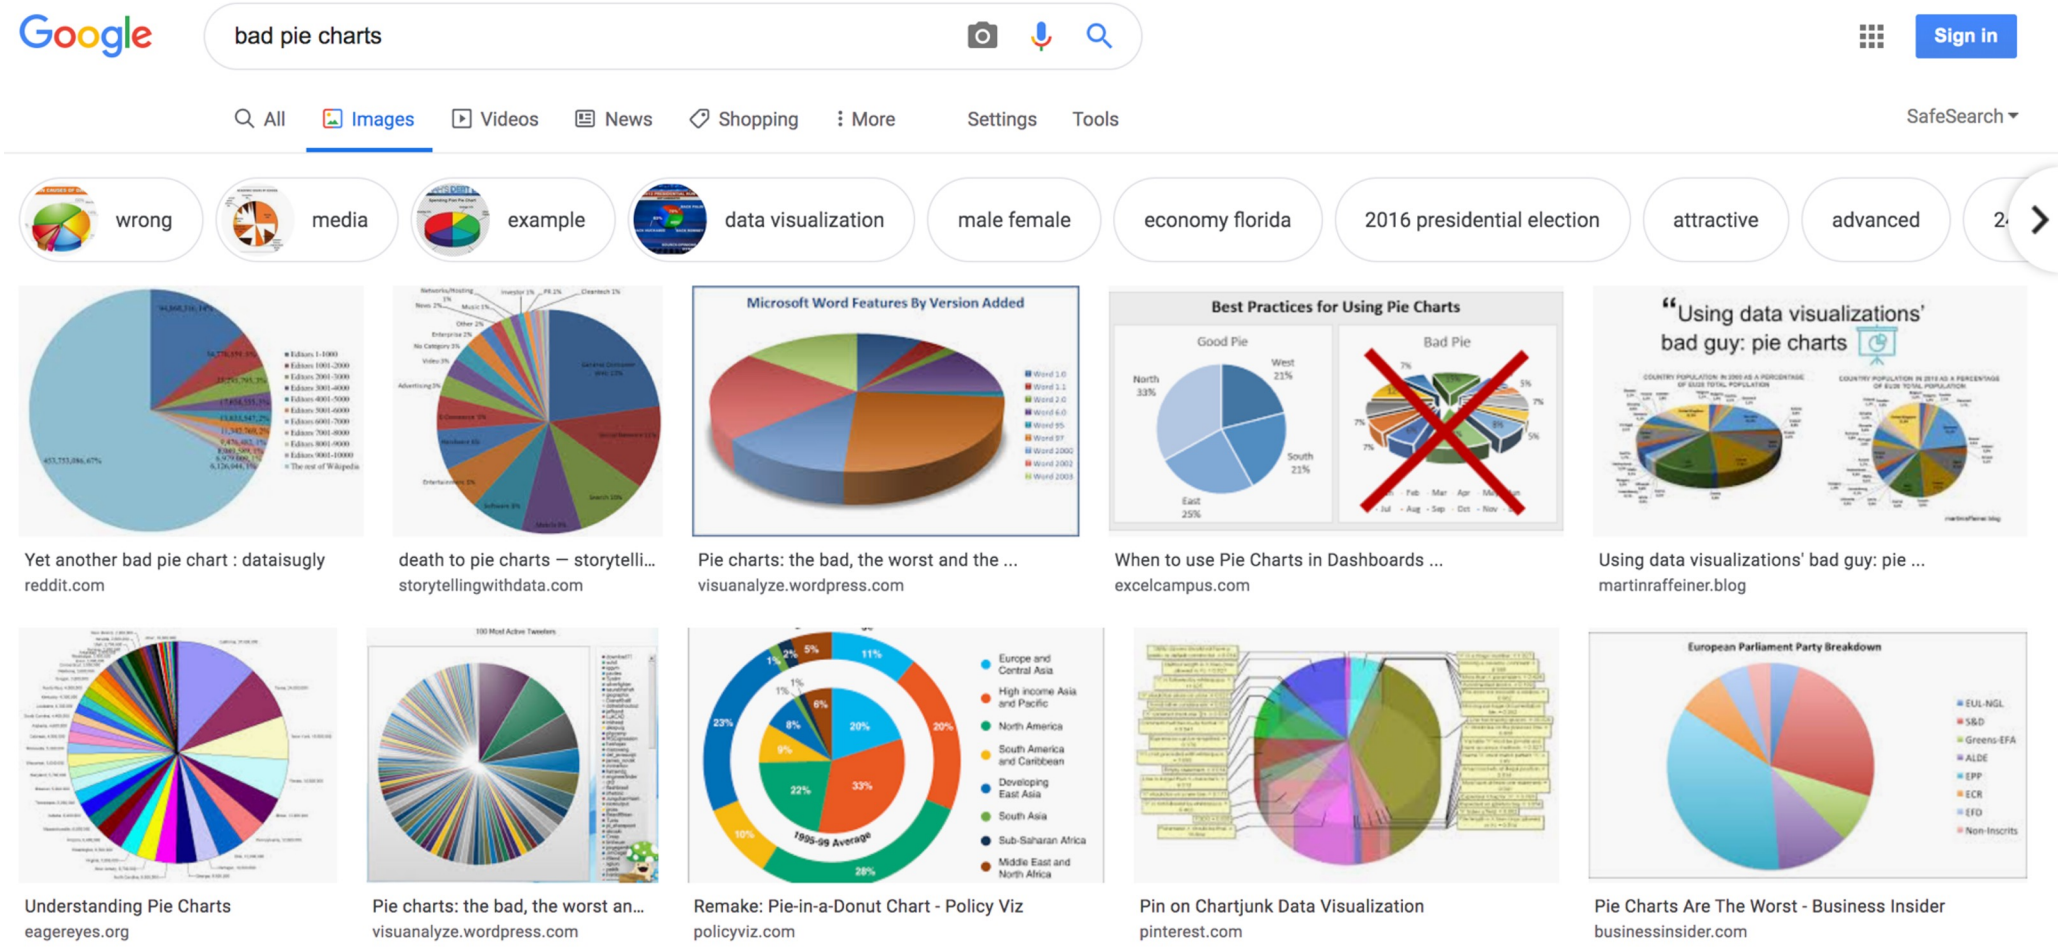
# Pie chart, where the slices will be ordered and plotted counter-clockwise:
labels = 'Frogs', 'Hogs', 'Dogs', 'Logs'
sizes = [15, 30, 45, 10]
explode = (0, 0.1, 0, 0)  # only "explode" the 2nd slice (i.e. 'Hogs')

fig1, ax1 = plt.subplots()
ax1.pie(sizes, explode=explode, labels=labels, autopct='%1.1f%%',
        shadow=True, startangle=90)
ax1.axis('equal')  # Equal aspect ratio ensures that pie is drawn as a circle.

plt.show()
```



Maybe the biggest problem with pie charts is that they have been so often done poorly...



Bar Chart

We perceive differences in height / length better than area…

`plt.bar()`

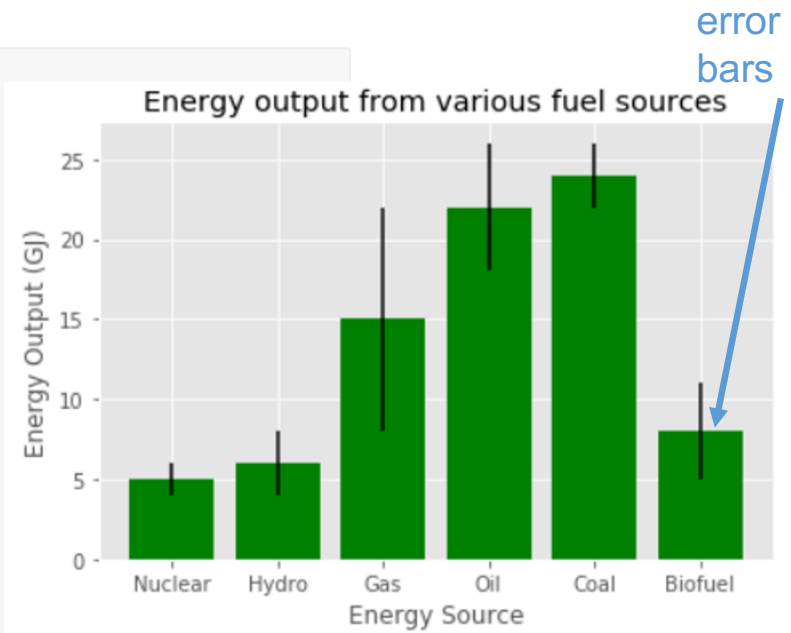
```
x = ['Nuclear', 'Hydro', 'Gas', 'Oil', 'Coal', 'Biofuel']
energy = [5, 6, 15, 22, 24, 8]
variance = [1, 2, 7, 4, 2, 3]

x_pos = [i for i, _ in enumerate(x)]

plt.bar(x_pos, energy, color='green', yerr=variance)
plt.xlabel("Energy Source")
plt.ylabel("Energy Output (GJ)")
plt.title("Energy output from various fuel sources")

plt.xticks(x_pos, x)

plt.show()
```



[Source: https://benalexkeen.com/bar-charts-in-matplotlib/]

Bar Chart

Horizontal version.

`plt.barh()`

```
x = ['Nuclear', 'Hydro', 'Gas', 'Oil', 'Coal', 'Biofuel']
energy = [5, 6, 15, 22, 24, 8]
variance = [1, 2, 7, 4, 2, 3]

x_pos = [i for i, _ in enumerate(x)]

plt.barh(x_pos, energy, color='green', xerr=variance)
plt.ylabel("Energy Source")
plt.xlabel("Energy Output (GJ)")
plt.title("Energy output from various fuel sources")

plt.yticks(x_pos, x)

plt.show()
```

Bar Chart

Multiple groups of bars…

```
import numpy as np

N = 5
men_means = (20, 35, 30, 35, 27)
women_means = (25, 32, 34, 20, 25)

ind = np.arange(N)    //
width = 0.35          [1,2,3,4,5]
plt.bar(ind, men_means, width, label='Men')
plt.bar(ind + width, women_means, width,
    label='Women')

plt.ylabel('Scores')
plt.title('Scores by group and gender')

plt.xticks(ind + width / 2, ('G1', 'G2', 'G3', 'G4', 'G5'))
plt.legend(loc='best')
plt.show()
```

add the offset here

Stacked Bar Chart

```
countries = ['USA', 'GB', 'China', 'Russia', 'Germany']
bronzes = np.array([38, 17, 26, 19, 15])
silvers = np.array([37, 23, 18, 18, 10])
golds = np.array([46, 27, 26, 19, 17])
ind = [x for x, _ in enumerate(countries)]

plt.bar(ind, golds, width=0.8, label='golds', color='gold', bottom=silvers+bronzes)
plt.bar(ind, silvers, width=0.8, label='silvers', color='silver', bottom=bronzes)
plt.bar(ind, bronzes, width=0.8, label='bronzes', color='#CD853F')

plt.xticks(ind, countries)
plt.ylabel("Medals")
plt.xlabel("Countries")
plt.legend(loc="upper right")
plt.title("2012 Olympics Top Scorers")

plt.show()
```
