Review: Least Squares Solution

Functional Find a line that minimizes the sum of squared residuals!

Given: $\{(x^{(i)}, y^{(i)})\}_{i=1}^m$

Compute:

ompute:

$$w^* = \arg\min_{w} \sum_{i=1}^{m} (y^{(i)} - w^T x^{(i)})^2$$

Least squares regression

https://www.activestate.com/resources/quick-reads/how-to-run-linear-regressions-in-python-scikit-learn/

Review: Least Squares Simple Case

$$\frac{d}{dw}\sum_{i=1}^N(y^{(i)}-wx^{(i)})^2=$$
 Derivative (+ chain rule)
$$=\sum_{i=1}^N2(y^{(i)}-wx^{(i)})(-x^{(i)})=0\Rightarrow$$

Distributive Property (and multiply -1 both sides)

$$0 = \sum_{i=1}^{N} y^{(i)} x^{(i)} - w \sum_{j=1}^{N} (x^{(j)})^{2}$$

Algebra

$$w = \frac{\sum_{i} y^{(i)} x^{(i)}}{\sum_{j} (x^{(j)})^2}$$

3

Learning Linear Regression Models

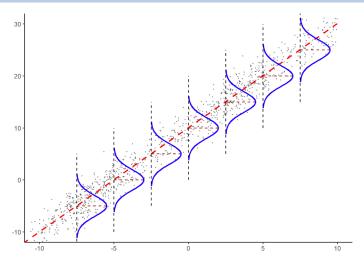

4

There are several ways to think about fitting regression:

- Intuitive Find a plane/line that is close to data
- Functional Find a line that minimizes the least squares loss
- Estimation Find maximum likelihood estimate of parameters

They are all the same thing...

• Assume $x \sim \mathcal{D}_X$ from some distribution. We then assume that

$$y = w^T x + \epsilon$$
 where $\epsilon \sim \mathcal{N}(0, \sigma^2)$

5

Probabilistic Assumptions

6

• Assume $x \sim \mathcal{D}_X$ from some distribution. We then assume that

$$y = w^T x + \epsilon$$
 where $\epsilon \sim \mathcal{N}(0, \sigma^2)$

• Equivalently,

$$p(y|x;w) = \mathcal{N}(w^T x, \sigma^2)$$

Why? Adding a constant to a Normal RV is still a Normal RV,

$$z \sim \mathcal{N}(m, P)$$
 $z + c \sim \mathcal{N}(m + c, P)$

for our case, linear regression $z \leftarrow \epsilon$ and $c \leftarrow w^T x$

MLE for Linear Regression

Given training data $\{(x^{(i)}, y^{(i)})\}_{i=1}^m$, maximize the likelihood!

$$\widehat{w} = \arg\max_{w} \log \prod_{i=1}^{m} p(x^{(i)}, y^{(i)}; w)$$

$$= \arg\max_{w} \log \prod_{i=1}^{m} p(x^{(i)}) p(y^{(i)}|x^{(i)}; w) \qquad \text{note } p(x^{(i)}) \text{ does not depend on } w!$$

$$= \arg\max_{w} \log \prod_{i=1}^{m} p(y^{(i)}|x^{(i)}; w) \qquad \text{subtracting a constant w.r.t. w does not affect the solution w!}$$

$$= \arg\max_{w} \sum_{i=1}^{m} \log p(y^{(i)}|x^{(i)}; w)$$

note model assumption! $p(y|x;w) = \mathcal{N}(w^Tx,\sigma^2)$

7

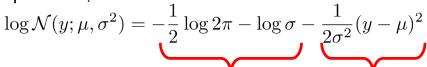

Univariate Gaussian (Normal) Distribution

Let's focuson 1d case. Let $\mu = w^T x$ for now.

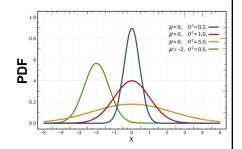

Gaussian (a.k.a. Normal) distribution with mean (location) μ and variance (squared scale) σ^2 parameters,

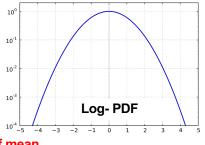

$$\mathcal{N}(y; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{1}{2}(y-\mu)^2/\sigma^2\right)$$

The logarithm of the PDF if just a negative quadratic,

Constant w.r.t. mean

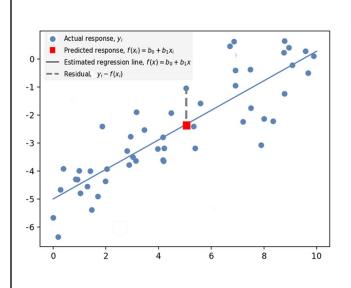

Quadratic Function of mean

MLE of Linear Regression

9

Substitute linear regression prediction into MLE solution and we have,

$$\arg\min_{w} \sum_{i=1}^{m} (y^{(i)} - w^{T} x^{(i)})^{2}$$

So for Linear Regression, MLE = Least Squares Estimation

C

Linear Regression Summary

| 0

1. The linear regression model (assumption),

$$y = w^T x + \epsilon$$
 where $\epsilon \sim \mathcal{N}(0, \sigma^2 I)$

2. For N iid training data fit using least squares,

$$w^{\text{OLS}} = \arg\min_{w} \sum_{i=1}^{N} (y^{(i)} - w^{T} x^{(i)})^{2}$$

3. Equivalent to maximum likelihood solution

A word on matrix inverses...

11

$$w^{\text{OLS}} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$$

Least squares solution requires inversion of the term,

$$(\mathbf{X}^T\mathbf{X})^{-1}$$

What is the issue?

May be non-invertible!

11

Invertible matrix

Invertible matrix: a matrix A of dimension n x n is called invertible if and only if there exists another matrix B of the same dimension, such that AB = BA = I, where I is the identity matrix of the same order.

$$A = \begin{bmatrix} 1 & 2 \\ 2 & 5 \end{bmatrix} \qquad AB = \begin{bmatrix} 1 & 2 \\ 2 & 5 \end{bmatrix} \begin{bmatrix} 5 & -2 \\ -2 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$
$$B = \begin{bmatrix} 5 & -2 \\ -2 & 1 \end{bmatrix} \qquad BA = \begin{bmatrix} 5 & -2 \\ -2 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 2 & 5 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

Pseudoinverse

13

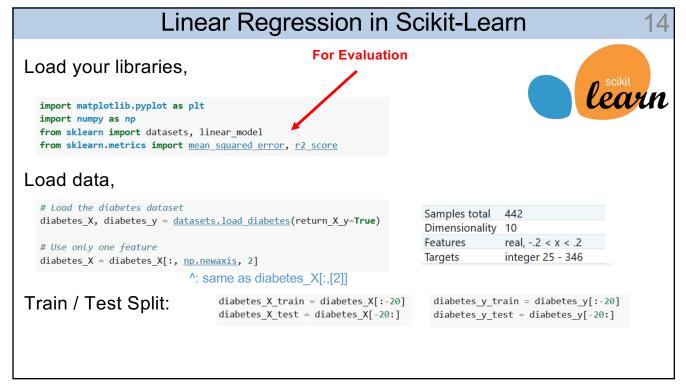

$$w^{\text{OLS}} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$$

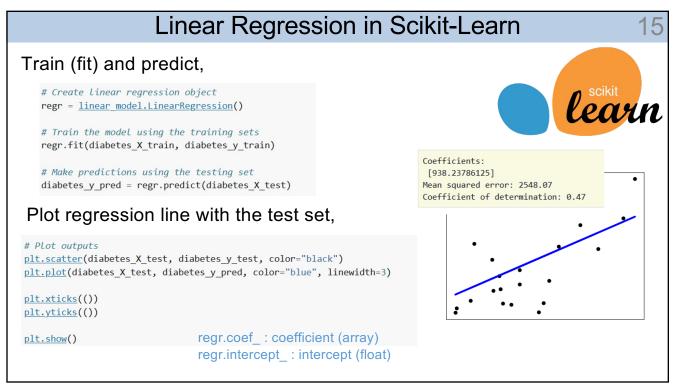

Use Moore-Penrose pseudoinverse ('dagger' notation)

$$w^{\text{OLS}} = (\mathbf{X}^T \mathbf{X})^{\dagger} \mathbf{X}^T \mathbf{y}$$

- Generalization of the standard matrix inverse for noninvertible matrices.
- Directly computable in most libraries
- In Numpy it is: linalg.pinv

13

15

Outline 16

- Linear Regression
- Least Squares Estimation
- Regularized Least Squares
- Logistic Regression

Alternatives to Ordinary Least Squares (OLS) 1

Recall: OLS solution

$$w^{\text{OLS}} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$$

Use Moore-Penrose pseudoinverse ('dagger' notation)

$$w^{\text{OLS}} = (\mathbf{X}^T \mathbf{X})^{\dagger} \mathbf{X}^T \mathbf{y}$$

Or, use L2 Regularized Least Squares (RLS)

$$w^{L2} = (\mathbf{X}^T \mathbf{X} + \lambda I)^{-1} \mathbf{X}^T \mathbf{y}$$

Q: why is this called regularized least squares?

17

Regularization

18

$$w^{\mathrm{L2}} = (\mathbf{X}^T \mathbf{X} + \lambda I)^{-1} \mathbf{X}^T \mathbf{y}$$

Turns out, w^{L2} is the solution of

$$w^{\text{L2}} = \arg\min_{w} \sum_{i=1}^{m} (y^{(i)} - w^T x^{(i)})^2 + \lambda \|w\|^2 \quad \text{recall: } \|w\| = \sqrt{\sum_{d=1}^{D} w_d^2}$$

λ: Regularization Strength

 $||w||^2$:Regularization Penalty

Prefers smaller magnitudes for w!

 λ very small: almost OLS

 λ very large: $w \approx 0$ and high trainset error

Challenges in ML

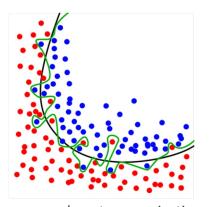

19

Okay, we have a training data. Why not learn the most complex function that can work flawlessly for the training data and be done with it? (i.e., classifies every data point correctly)

<u>Extreme example:</u> Let's memorize the data. To predict an unseen data, just follow the label of the closest memorized data.

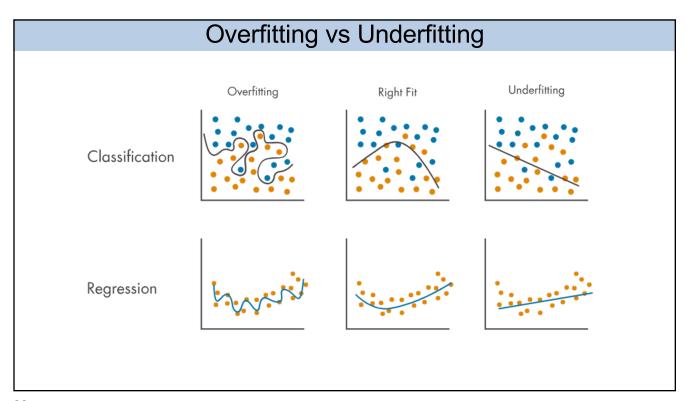

Doesn't generalize to unseen data – called *overfitting* the training data.

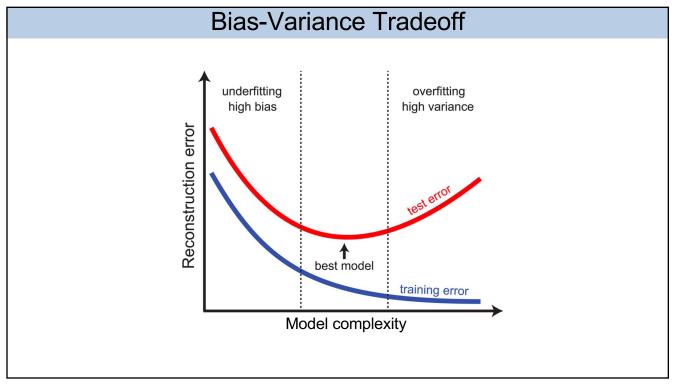

<u>Solution:</u> Fit the train set but don't "over-do" it. This is called regularization.

green: almost memorization
black: true decision boundary

19

21

Regularization

- 1d case
 - Suppose that $y = wx + \epsilon$, and the true model is w = 0 ($y = \epsilon$)
 - However, OLS is highly probable to 'exaggerate' the effect of x to decrease train set error: (overfitting) $\sum_{u(i)} u(i) x(i)$

 $w = \frac{\sum_{i} y^{(i)} x^{(i)}}{\sum_{j} (x^{(j)})^2}$

 On the other hand, RLS will try to balance the train set error and the penalty caused by the large norm

$$w^{RLS} = \frac{\sum_{i} y^{(i)} x^{(i)}}{\sum_{j} (x^{(j)})^{2} + \lambda} |w^{RLS}| < |w^{OLS}|$$

Regularization

23

$$w^{\text{RLS}} = (\mathbf{X}^T \mathbf{X} + \lambda I)^{-1} \mathbf{X}^T \mathbf{y}$$

Turns out, w^{RLS} is the solution of

$$w^{\text{L2}} = \arg\min_{w} \sum_{i=1}^{m} (y^{(i)} - w^T x^{(i)})^2 + \lambda \|w\|^2 \quad \text{recall: } \|\mathbf{w}\| = \sqrt{\sum_{d=1}^{D} w_d^2}$$

λ: Regularization
Strength

 $\|w\|^2$:Regularization Penalty

In short, the benefits of L2-RLS

- No need to worry about the estimator being undefined (due to matrix inversion)
- Avoid overfitting (if λ is chosen well)!

23

Scikit-Learn: L2 Regularized Regression

24

sklearn.linear_model.Ridge

class sklearn.linear_model.Ridge(alpha=1.0, *, fit_intercept=True, normalize='deprecated', copy_X=True, max_iter=None, tol=0.001, solver='auto', positive=False, random_state=None) 1 [source]

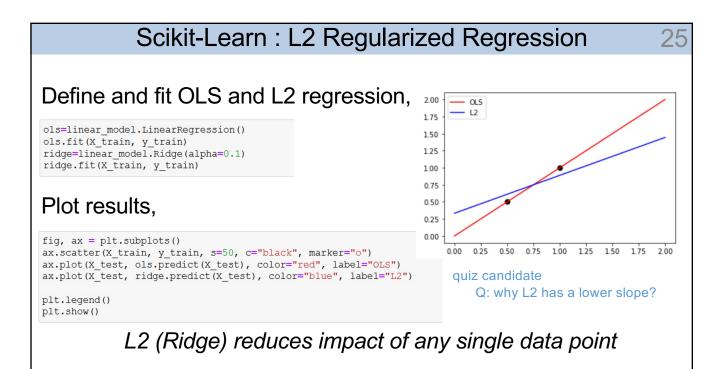

Minimizes the objective function:

$$||y - Xw||^2_1 + alpha * ||w||^2_2$$

Alpha is what we have been calling λ

alpha: {float, ndarray of shape (n_targets,)}, default=1.0

Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to 1 / (2C) in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

25

Notes on L2 Regularization

26

- Feature weights are "shrunk" towards zero statisticians often call this a "shrinkage" method
- Common practice: Do **not** penalize bias (y-intercept, w_D) parameter,

$$\min_{w} \sum_{i} (y^{(i)} - w^{T} x^{(i)})^{2} + \frac{\lambda}{2} \sum_{d=1}^{D-1} w_{d}^{2}$$

Recall: we enforced $x_D^{(i)} = 1$ so that w_D encodes the intercept

• Penalizing intercept will make solution depend on origin for Y. i.e., add a constant c to $y^{(i)}$'s \Longrightarrow the solutions changes!

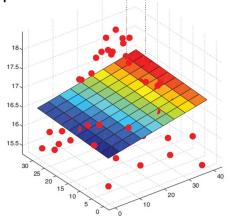

Moving to higher dimensions...

Often we simplify this by including the intercept into the weight vector,

$$\widetilde{w} = \begin{pmatrix} w_1 \\ \vdots \\ w_D \\ b \end{pmatrix} \qquad \widetilde{x} = \begin{pmatrix} x_1 \\ \vdots \\ x_D \\ 1 \end{pmatrix} \qquad y = \widetilde{w}^T \widetilde{x}$$

$$\widetilde{x} = \left(\begin{array}{c} x_1 \\ \vdots \\ x_D \\ 1 \end{array}\right)$$

$$y = \widetilde{w}^T \widetilde{x}$$

Since:

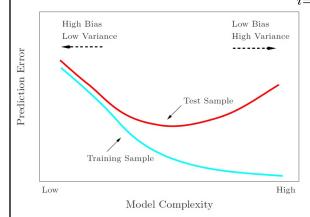

$$\widetilde{w}^T \widetilde{x} = \sum_{d=1}^{D} w_d x_d + b \cdot 1$$
$$= w^T x + b$$

27

Choosing Regularization Strength

We need to tune regularization strength to avoid over/under fitting...

$$w^{L2} = \arg\min_{w} \sum_{i=1}^{m} (y^{(i)} - w^{T} x^{(i)})^{2} + \lambda ||w||^{2}$$

Recall bias/variance tradeoff

High regularization reduces model complexity: increases bias / decreases variance

Q: How should we properly tune λ ?

cross validation!
